

When I first started using Claude Code over the summer, I started out with meaningless projects that I would finish and never touch again. This is when I decided to take on a project that I would be able to apply to my everyday life to make a task easier. I landed on a financial web application to help me track the stock market. I wanted to create this because most apps like Sofi and Fidelity only share basic information about stocks and on top of that it's hard to interpret. My solution to this was to create an app that shared all the data a user would need to make an informed decision when investing in a stock while having easy access to explanations on what the numbers mean. There are also other basic functions such as watch lists, news articles, reporting dates, etc.

The reflection I had from this week's lessons was my products lack of user validation. Throughout the entire building process, I have only been going off my own ideas and haven't run the build by anybody that would be a potential user. To remedy this, I had my dad look at the design and give me input on anything he thought should be changed for accessibility or usability. Overall, he liked the general layout but suggested that I should add a function that allows csv's to be uploaded with portfolio information to keep all a user's information organized in one location. He also suggested some small additions such as company summaries and dividend histories. I am hoping that a little more user input could help me refine my product into something people would implement into their lives.
